FAST ALGORITHMS FOR FINDING A SUBDIRECT DECOMPOSITION AND INTERESTING CONGRUENCES OF FINITE ALGEBRAS

JIRI DEMEL

A fast algorithm is suggested for finding a subdirect decomposition of a given finite algebra into subdirectly irreducible ones. This algorithm is an essential improvement of that given in [4]. As a by-product, fast algorithms are presented for finding some interesting congruences of the given algebra.

All algebras are supposed to be finite and given by tables of their operations.

A fast algorithm is suggested for finding a subdirect decomposition of a given finite algebra into subdirectly irreducible ones. This algorithm is an essential improvement of that given in [4]. As a by-product, fast algorithms are presented for finding some interesting congruences of the given algebra.

All algebras are supposed to be finite and given by tables of their operations.

Subdirect product is a useful construction of "complicated" algebras from "simpler" ones. Also, the parallel composition of automata [7] can be regarded as a subdirect product. In [3] a fast algorithm is presented deciding whether a given automaton (Mealy, Moore or Medvedev) is subdirectly irreducible.

Since subdirect products and subdirect irreducibility are closely related to congruences, this result is based on an algorithm finding minimal non-identical congruences. In [5] this method is generalized to algebras and the algorithm is asymptotically improved. Also, Hopcroft's and Karp's algorithms [8] and [9], originally designed for automata, can be modified to search for interesting congruences of an algebra. The present paper can be viewed as a free continuation of the papers [3] and [5].

By an algebra we mean a pair $\mathcal{A} = (A, F)$ where $A$ is a finite set and $F$ is a finite set of operations. An operation $f$ is a mapping $f : A^s \rightarrow A$ ($A^s$ is the $s$-th power of $A$); the number $s$ is the arity of $f$ and we shall denote it by $\text{ar}(f)$.

Throughout the paper $n$ denotes $\text{card}(A)$ and $r$ is the maximal arity of operations. All the running times of algorithms will be given for classes of algebras with the same number of operations that have arity at most $r$. 

121
A congruence on an algebra $\mathcal{U} = (A, F)$ is an equivalence $\varepsilon$ on $A$ satisfying the substitution property:

$(SP)$ for every operation $f \in F$ with $\ar(f) = s > 0$ whenever we have an $s$-tuple $(x_1, \ldots, x_s) \in A^s$ and an element $y \in A$ such that $(x_i, y) \in \varepsilon$ for some $i$, $1 \leq i \leq s$, then $(f(x_1, \ldots, x_{i-1}, y, x_{i+1}, \ldots, x_s), f(x_1, \ldots, x_s)) \in \varepsilon$.

On every algebra we have at least two congruences — the identical congruence, denoted by $A$, i.e. $(x, y) \in A$ iff $x = y$, and the trivial congruence denoted by $V$, i.e. $V = A^2$. Congruences as equivalences are partially ordered by inclusion.

If $\varepsilon, \delta$ are equivalences, we denote by $\varepsilon \wedge \delta$ the meet of $\varepsilon, \delta$, i.e. their intersection, and by $\varepsilon \vee \delta$ the join of $\varepsilon, \delta$, i.e. the smallest equivalence containing both $\varepsilon$ and $\delta$.

It is well-known that if $\varepsilon, \delta$ are congruences, so are $\varepsilon \wedge \delta$ and $\varepsilon \vee \delta$.

Let $\mathcal{U} = (A, F), \mathcal{U}_i = (A_i, F_i)$ for $i = 1, \ldots, m$, be algebras with the same arities of operations. Then $\mathcal{U}$ is a subdirect product of the algebras $\mathcal{U}_i, i = 1, \ldots, m$, if $\mathcal{U}$ is a subalgebra of their direct product and for any $i$ and any $v \in A_i$ there is an element $(x_1, \ldots, v, \ldots, x_m) \in A$.

The algebra $\mathcal{U}$ is called subdirectly irreducible if, whenever $\mathcal{U}$ is a subdirect product of $\mathcal{U}_i, i = 1, \ldots, m$, then there is $j$ such that the canonical projection $\pi_j : \mathcal{U} \to \mathcal{U}_j$ is an isomorphism.

For more details see e.g. [6].

**Theorem 1.** ([2]) Every algebra is isomorphic to a subdirect product of subdirectly irreducible algebras.

**Theorem 2.** ([2]) If an algebra $\mathcal{U}$ is a subdirect product of algebras $\mathcal{U}_i, i = 1, \ldots, m$, then there exist congruences $\varepsilon_i, i = 1, \ldots, m$, on $\mathcal{U}$ such that $\mathcal{U}_i \cong \mathcal{U}/\varepsilon_i$ for all $i = 1, \ldots, m$ and $\{\varepsilon_i \mid i = 1, \ldots, m\}$ is a separative system of congruences, i.e.

$\bigwedge_{i=1}^{m} \varepsilon_i = A$.

**Theorem 3.** ([2]) A finite algebra is subdirectly irreducible iff either it has exactly one minimal non-identical congruence or it has only one element.

**Corollary 4.** An algebra $\mathcal{U}/\varepsilon$ is subdirectly irreducible iff

$(\text{Max})$ there exists a pair of distinct elements $(x, y)$ of $\mathcal{U}$ such that $\varepsilon$ is a maximal congruence on $\mathcal{U}$ with $(x, y) \notin \varepsilon$, i.e. $(x, y) \notin \varepsilon$ and whenever $\varepsilon' \supseteq \varepsilon$, $\varepsilon' \neq \varepsilon$ then $(x, y) \notin \varepsilon'$ for any congruence $\varepsilon'$.

The above Theorems and Corollary 4 offer a strategy for construction of algebras $\mathcal{U}_i, i = 1, \ldots, m$, of which the given algebra $\mathcal{U}$ is a subdirect product: Having constructed a system of congruences $\{\varepsilon_i \mid i = 1, \ldots, m\}$ satisfying (Sep) and (Max), one can simply construct $\mathcal{U}_i$ as $\mathcal{U}/\varepsilon_i$. The construction of each quotient-algebra $\mathcal{U}/\varepsilon_i$ can be carried out in time $O(p^p)$ where $p$ is the number of all congruence classes of $\varepsilon_i$.

Note that if $m \geq n$, then at least one congruence can be deleted from the system without violating (Sep) and (Max).
So the original problem has been reduced to the problem

(P1) Given an algebra $\mathfrak{A} = (A, F)$, find a system of congruences $S = \{\varepsilon_i | i = 1, \ldots, m\}$ fulfilling (Sep), (Max) and $m < n$.

The problem (P1) will be solved by the algorithm SUBDECOMP and Theorem 9 using a procedure MAXNOTTWO which solves the following problem (P2):

(P2) Given an algebra $\mathfrak{A} = (A, F)$ and a pair $(v, w) \in A^2 \setminus A$, find a congruence $\varepsilon$ such that

(i) $(v, w) \notin \varepsilon$;

(ii) $\varepsilon$ is maximal with respect to (i), i.e. if $\gamma \supset \varepsilon$, $\gamma \neq \varepsilon$ then $(v, w) \notin \gamma$

for any congruence $\gamma$.

The main part of the procedure MAXNOTTWO is formed by the procedure SAFEPARTITION. In addition, two procedures MAXINEQUIV and MINCONG are used to solve the following problems (P3) and (P4) concerning congruences:

(P3) Given an algebra $\mathfrak{A}$ and an equivalence $\delta \neq V$, find the greatest congruence $\varepsilon \equiv \delta$.

This problem can be solved by a slight modification of Hopcroft’s algorithm [8] for minimization of finite automata.

(P4) Given an algebra $\mathfrak{A}$, a congruence $\delta$ on $\mathfrak{A}$ and a pair $(x, y) \notin \delta$, find the minimal congruence $\varepsilon$ with $\delta \subseteq \varepsilon$ and $(x, y) \in \varepsilon$.

This problem can be solved by a modification of Hopcroft’s and Karp’s algorithm [9] originally designed for testing equivalence of automata.

There is a natural generalization of both (P2) and (P3):

(P5) Given an algebra $\mathfrak{A} = (A, F)$ and a relation $R \subseteq A^2 \setminus A$, find a congruence $\varepsilon$ with

(i) $\varepsilon \cap R = \emptyset$;

(ii) $\varepsilon$ is maximal with respect to (i).

Although this is not going to be used for the problem of subdirect decomposition, it represents an interesting problem in its own right. Its solution is discussed at the end of the paper.

To simplify the description of the algorithms given below, the problems stated above can be, without loss of generality, restricted to unary algebras only. Indeed, this follows from the following observation: As far as the substitution property is considered, the following procedures have no effect:

(i) each nullary operation is omitted,

(ii) each $s$-ary operation $f$ is replaced by $s \cdot n^{s-1}$ unary operations obtained by fixing $s - 1$ entries in $f$.

Hence each algebra can be converted to a unary algebra with the same congruences (considered as equivalences on the same set) in time proportional to the size of all tables of operations. In most cases, this does not influence asymptotically the total time. However the need of the conversion can be avoided by modifying the algorithms to deal with arbitrary algebras.

Thus the descriptions of algorithms will be given for unary algebras only although time bounds will be given for arbitrary algebras.
The conversion of an arbitrary algebra to unary algebra with the same congruences enables us to modify some algorithms, originally designed for automata, to be used for algebras. Names of unary operations correspond to input symbols, the elements of the underlying set of the algebra correspond to states of the automaton. Congruences of the algebra coincide with congruences on the states of the automaton.

**Lemma 5 ([8]).** There exists a procedure MAXINEQUIV(δ) that replaces a given equivalence δ by the greatest congruence contained in δ and that needs time at most \(O(n' \cdot \log n)\).

**Lemma 6 ([9]).** There exists a procedure MINCONG1(δ) that replaces a given equivalence δ by the smallest congruence \(\varepsilon \supseteq \delta\) and that needs time at most \(O(n')\) for \(r > 1\) and \(O(n \cdot G(n))\) for \(r = 1\), where \(G(n) = \min \{i \in \mathbb{N} \mid \log \log \ldots \log n \leq 1\}\).

In the above algorithms MAXINEQUIV and MINCONG1 equivalence δ should be stored and maintained in different data structures. In MAXINEQUIV, classes of equivalence δ are represented by doubly linked lists and by an array that assigns to each element the name of the class in which it is contained. In this data structure operations Delete and Insert can be performed in a constant time.

In MINCONG1, the system of disjoint sets (i.e. classes of the equivalence) is represented by the tree data structure ([10], [11], [1]) for quick operations Union and Find. In this data structure \(k \geq n\) operations Find and \(n - 1\) Unions can be performed in time \(O(k \cdot G(n))\), where \(G(n) = \{i \in \mathbb{N} \mid \log \log \ldots \log n \leq 1\}\) but if \((k/n)\) grows sufficiently (e.g. if \(k/n \geq \log \log n\)) then the time needed for \(k\) Finds and \(n - 1\) Unions is \(O(k)\).

Suppose that for a given element \(x\) and a given equivalence \(\delta\) the procedure FIND(\(x, \delta\)) yields the name of the equivalence class \(c\) in \(\delta\) such that \(x \in c\). Further, suppose that for given two names of classes \(a, b\) in \(\delta\), the procedure UNION(\(a, b, \delta\)) replaces the classes \(a, b\) by their union and call the resulting class \(c\).

Both the data structures mentioned above (i.e. the data structures used in MAXINEQUIV and MINCONG1) cannot be maintained simultaneously, but they can be easily converted each to the other in time \(O(n)\).

We shall denote by \(\varepsilon\) the set of names of congruence classes of equivalence \(\varepsilon\).

**Lemma 7.** There exists a procedure MINCONG(\(\delta, x, y, \text{LIST}\)) that replaces a congruence \(\delta\) by the smallest congruence \(\varepsilon\) containing both \(\delta\) and \((x, y)\), and in LIST returns a sequence of all triples \((a, b, c)\) of names of congruence classes such that during the execution of MINCONG, classes \(a, b\) were replaced by \(a \cup b\) and the resulting class was called \(c\). The time needed by the procedure MINCONG is \(O(p')\) for \(r > 1\) and \(O(p \cdot G(p))\) for \(r = 1\), where \(p\) is the number of congruence classes of \(\delta\) and the function \(G\) is as given in Lemma 6.
Proof. One can either apply procedure MINCONG1 to the quotient-algebra \( \mathfrak{A}/\delta \) or (which is, in fact, the same) make a further modification of the algorithm to deal with representatives of congruence classes only.

Lemma 8. There exist procedures \( \text{JOIN}(\alpha, \beta) \) and \( \text{MEET}(\alpha, \beta) \) that produce equivalences \( \alpha \lor \beta \) and \( \alpha \land \beta \) in time \( O(n) \).

Now, we can describe the procedure SUBDECOMP using the procedure MEET and MAXNOTTWO. The latter will be described below.

Procedure SUBDECOMP:

```
begin S := \emptyset; \delta := \mathcal{V};
while \delta \neq A do
  begin
    choose \( c \in \delta \) with \( \text{card}(c) \geq 2 \);
    choose distinct elements \( v, w \in c \);
    \epsilon := \text{MAXNOTTWO}(v, w);
    \delta := \text{MEET}(\epsilon, \delta);
    insert \epsilon \text{ into } S
  end;
return S
end;
```

Theorem 9. The procedure SUBDECOMP solves (P1) in time \( O(n \cdot t + n^2) \), where \( t \) is time needed for one execution of procedure MAXNOTTWO which solves problem (P2).

Proof. The proof of correctness is easy. The proof of time bound is based on the fact that during repetition of the while-loop the number of classes of \( \delta \) is increased.

The procedure MAXNOTTWO solving (P2) is based on the following lemma:

Lemma 10. Let \( \mathfrak{A} = (A, F) \) be an algebra, let \( v, w \in A \), \( v \neq w \). Let \( \beta \) be a congruence and \( \delta \) an equivalence such that

(i) \( (v, w) \notin \delta \) and \( \beta \subseteq \delta \);
(ii) every congruence \( \gamma \supseteq \beta \) containing \( (x, y) \notin \delta \) contains \( (v, w) \).

Then the greatest congruence \( \epsilon \) contained in \( \delta \) (i.e. the solution of (P3)) is also a greatest congruence not containing \( (v, w) \) (i.e. the solution of (P2)).

Proof. The statement follows from the fact that (ii) is equivalent to

(ii') every congruence \( \gamma \supseteq \beta \) not containing \( (v, w) \) is contained in \( \delta \).

The congruence \( \epsilon \) is the greatest one fulfilling both \( \beta \subseteq \epsilon \) and \( (v, w) \notin \epsilon \), so it is one of maximal congruences not containing \( (v, w) \).
An equivalence $\delta$ from Lemma 10 can be constructed by a procedure 

**SAFEPARTITION($v, w$)** described below.

**Procedure SAFEPARTITION($v, w$):**

```plaintext
begin $eta := \Delta$; $B := \beta \setminus \{\text{FIND}(v, \beta)\}$;
while $B \neq \emptyset$ do
begin
  choose $e \in B$;
  choose $x \in e$;
  copy $\beta$ into $x$;
  MINCONG($x, v, x, \text{LIST}$);
  if FIND($v, x$) = FIND($v, a$) then $B := B \setminus \{e\}$
  else for all $(a, b, c) \in \text{LIST}$ do
    begin
      UNION($a, b, c, \beta$);
      if $a \in B$ & $b \in B$ then $B := (B \setminus \{a, b\}) \cup \{c\}$
      if $a \in B$ & $b \notin B$ then $B := B \setminus \{a\}$
      if $a \notin B$ & $b \in B$ then $B := B \setminus \{b\}$
    end
  end
  copy $\beta$ into $\beta$;
  $a := \text{FIND}(v, \beta)$;
end
```

all classes from $\beta \setminus \{a\}$ replace by their union;

**return $\beta$**

**Theorem 11.** The procedure SAFEPARTITION produces the equivalence $\delta$ fulfilling the assumptions of Lemma 10 in time $O(n^2 \cdot G(n))$ if $r = 1$ and $O(n^{r+1})$ if $r \geq 2$.

**Proof.** The proof of the time bound is easy since card($B$) decreases in each repetition of the while-loop. To prove the correctness, it suffices to prove that after each repetition of the while-loop, the following hold:

(a) $\beta$ is a congruence;
(b) $B$ is a subset of $\beta$.

(c) Denoting $a = \text{FIND}(v, \beta)$ and $D = \beta \setminus (B \cup \{a\})$ we have:

if $x \in a$ and $y \in \bigcup\{d \mid d \in D\}$ then

(c1) every congruence $\gamma \equiv \beta$ containing $(x, y)$ contains $(v, w)$. 

126
The proof of (a) and (b) is easy, let us prove (c). We proceed by induction.

At the beginning we have \( D = \emptyset \), hence (c) holds. Assume (c) was true at the end of the previous repetition of the while-loop and let \( B \neq \emptyset \). Then \( x \in e \in B \) is chosen and \( \textsc{mincong}(x, v, x, \textsc{list}) \) is executed. If \( (v, w) \in \mathcal{A} \), then (c1) holds for all \((z, y)\) with \( z \in a \) and \( y \in e \); (c) holds. If \( (v, w) \notin \mathcal{A} \), then all unions just formed in \( x \) are now repeated in \( \beta \) and, at the same time, \( B \) is maintained either by replacing \( a, b \) by \( c \), which does not change \( \cup \{d \mid d \in D\} \), or by deleting \( a \) or \( b \) from \( B \). In the latter case no new elements are inserted into \( D \) and \( \cup \{d \mid d \in D\} \) can increase only by increasing some classes that have already been in \( D \). Also the class \( a \) can increase. But exactly those classes are now in \( \beta = x \). Hence condition (c) holds after every repetition of the while-loop.

After finishing the while-loop, an equivalence \( \delta \) is produced with exactly two classes \( a \) and \( \cup \{d \mid d \in D\} \). From (c) it follows that after the last repetition of the while-loop \( \delta \) fulfils the assumptions of Lemma 10, which concludes the proof.

The procedure \textsc{maxnottwo} can be described as follows:

**Procedure** \textsc{maxnottwo}(v, w):

\[
\begin{align*}
\delta & := \textsc{safepartition}(v, w); \\
\text{maxinequiv}(\delta); \\
\text{return} \quad \delta
\end{align*}
\]

**Theorem 12.** The procedure \textsc{maxnottwo} solves \((P2)\) in time \( O(n^2 \cdot G(n)) \) if \( r = 1 \) and \( O(n^{r+1}) \) if \( r \geq 2 \).

**Proof** follows immediately from Theorem 11 and Lemma 10.

**Corollary 13.** The procedure \textsc{subdecomp} solves \((P1)\) in time \( O(n^3 \cdot G(n)) \) if \( r = 1 \) and \( O(n^{r+2}) \) if \( r \geq 2 \).

Finally, let us discuss the solution of \((P5)\). If \( R \) is a complement of an equivalence \( \delta \), then \((P5)\) coincides with \((P3)\) and is solved by the procedure \textsc{maxinequiv}. If \( R = \{(u, v)\} \) then \((P5)\) coincides with \((P2)\) and it is reduced to \((P3)\) using the procedure \textsc{safepartition}.

If \( 0 < \text{card}(R) \leq k \) for some fixed \( k \) then the reduction of \((P5)\) to \((P3)\) can be carried out by a similar method and with the same time bound as in \textsc{safepartition}. For this purpose Lemma 10 should be slightly generalized:

**Lemma 14.** Let \( \mathbb{A} = (A, F) \) be an algebra, let \( R \subseteq A^2 \setminus A \), \( R \neq \emptyset \). Let \( \beta \) be a congruence and \( \delta \) an equivalence such that

(i) \( R \cap \delta = \emptyset \) and \( \beta \subseteq \delta \),

(ii) for every congruence \( \gamma \supseteq \beta \) containing \( (x, y) \notin \delta \) we have \( \gamma \cap R = \emptyset \).

Then the greatest congruence \( \varepsilon \) contained in \( \delta \) (i.e. the solution of \((P3)\)) is also a greatest congruence disjoint with \( R \) (i.e. the solution of \((P5)\)).
Procedure SAFEPARTITION1(R):
begin
  \( \beta := A; \)
  \( \bar{R} := \{ x \mid (x, y) \in R \text{ or } (y, x) \in R \text{ for some } y \in A \}; \)
  for all \( (x, y) \in R^2 \setminus R \) do
  begin
    copy \( \beta \) into \( \alpha; \)
    MINCONG(\( \alpha \), \( x \), \( y \), LIST);
    if \( R \cap \alpha = \emptyset \) then copy \( \alpha \) into \( \beta \)
    else insert \( \{x, y\} \) to \( R \)
  end;
  \( B := \{ a \in \beta \mid a \cap \bar{R} = \emptyset \}; \)
  \( C := \{ a \in \beta \mid a \cap \bar{R} \neq \emptyset \}; \)
  while \( B \neq \emptyset \) do
  begin
    choose \( e \in B \) and \( x \in e; \)
    for all \( a \in C \) do
    begin
      choose \( y \in a; \)
      copy \( \beta \) into \( \alpha; \)
      MINCONG(\( \alpha \), \( x \), \( y \), LIST);
      if \( \alpha \cap R = \emptyset \) then
      begin
        for all \( (a, b, c) \in LIST \) do
        begin
          UNION(\( a, b, c, \beta \));
          if \( a \in B \) and \( b \in B \)
          then \( B := (B \setminus \{a, b\}) \cup \{c\} \)
          else \( B := B \setminus \{a, b\} \);
          if \( a \in C \) or \( b \in C \)
          then \( C := (C \setminus \{a, b\}) \cup \{c\} \)
        end;
      end;
    end;
  end;
  S2: \( B := B \setminus \{e\} \)
  end;
  copy \( \beta \) into \( \delta; \)
  all classes from \( \delta \setminus C \) replace by their union;
  return \( \delta \)
end;
Theorem 15. The procedure SAFEPARTITION1 produces the equivalence $\delta$ fulfilling the assumptions of Lemma 14. If $\text{card}(R) \leq k$ for some fixed $k$ then it requires time $O(n^3 \cdot G(n))$ for $r = 1$ and $O(n^{r+1})$ for $r \geq 2$.

Proof is similar to that of Theorem 11. After each repetition of the while-loop the following hold:
(a) $\beta$ is a congruence;
(b) $B, C$ are disjoint subsets of $\beta$;
(c) denoting $D = \beta \setminus (B \cup C)$ we have:

\[ \text{if } x \in \bigcup \{ c \mid c \in C \} \text{ and } y \in \bigcup \{ d \mid d \in D \} \text{ then for every congruence } \gamma \supseteq \beta \text{ if } (x, y) \in \gamma \text{ then } \gamma \cap R = \emptyset.\]

Details of the proof are left to the reader.

Having a congruence $\varepsilon$ such that $\varepsilon \cap R = \emptyset$ the problem (P5) can be solved directly by the following simple procedure. Note that as $\varepsilon$ we can always use congruence $\Delta$.

Procedure MAXNOT($R, \varepsilon$)

begin

$SET := \{(a, b) \mid a, b \in \varepsilon, a \neq b, (a \times b) \cap R = \emptyset\}$;

$\delta := \varepsilon$;

for all $(a, b) \in SET$ do

begin

choose $x \in a$ and $y \in b$;

copy $\delta$ into $\alpha$;

MINCONG($a, x, y, LIST$);

if $a \cap R = \emptyset$ then copy $a$ into $\delta$

end;

$\varepsilon := \delta$;

end;

Theorem 16. Let $\varepsilon$ be a congruence such that $\varepsilon \cap R = \emptyset$. Denote $s = \text{card}(SET)$, $p = \text{card}(R)$ and $q = \text{card}(\varepsilon)$. Then procedure MAXNOT($R, \varepsilon$) will produce a solution of (P5) in time $O(q^3 p + s(q^2 + n + p))$ if $r \geq 2$ and $O(q^3 p + s(q \cdot G(q) + n + p))$ if $r = 1$.

If we have no previous information concerning congruence $\varepsilon$ such that $\varepsilon \cap R = \emptyset$, we may use $\varepsilon = \Delta$. In this case time bound will be $O(n^2 + n^{r+2})$.

(Received August 28, 1981.)
